===== LP/DATA README (formerly index) =====

To reduce transmission times, linear programming test problems
are stored in a compressed format; issue the netlib request

    send emps.f from lp/data

to obtain a Fortran 77 Subset program for expanding the test problems
into MPS-standard input form. The program includes comments giving
test data. To get a (more efficient and convenient) C version of this
program (without the test data), issue the netlib request

    send emps.c from lp/data

If you are not familiar with MPS files, see Chapter 9 of "Advanced
Linear Programming" by Bruce A. Murtagh, McGraw-Hill, 1981,
or look at the information on MPS files in

    http://www.mcs.anl.gov/home/otc/Guide/faq/

All the material described here is now available by ftp from
netlib.bell-labs.com (login: anonymous; Password: your E-mail address;
cd /netlib/lp/data). If you can, please use ftp to obtain the larger
problems. Note that the *.Z files in lp/data must be copied in binary
mode and uncompressed two ways: first with uncompress, then with emps.
If you are using a Unix system and your solver reads standard input,
you can save some disk space by executing, e.g.,
    zcat pilot.Z | emps | solver
On some Unix systems and with solvers that require a named file,
you may also be able to use a named pipe, e.g.,
    /etc/mknod pilot.mps p
    zcat pilot.Z | emps >pilot.mps & solver pilot.mps
    rm pilot.mps

The "Kennington" problems, sixteen problems described in "An Empirical
Evaluation of the KORBX Algorithms for Military Airlift Applications"
by W. J. Carolan, J. E. Hill, J. L. Kennington, S. Niemi, S. J.
Wichmann (Operations Research vol. 38, no. 2 (1990), pp. 240-248),
are available only by ftp: login as above, and cd lp/data/kennington .
More details appear in lp/data/kennington/readme .

People who use EBCDIC systems may wish to issue the netlib request

    send ascii from lp/data

to get a listing of the distinct character codes that appear in the
compressed LP data files -- for the uncompression routines to work,
these distinct ASCII characters must be translated into distinct
EBCDIC
characters.

The column and nonzero counts in the PROBLEM SUMMARY TABLE below
exclude slack and surplus columns and the right-hand side vector, but
include the cost row. We have omitted other free rows and all but the
first right-hand side vector, as noted below. The byte count is for
the compressed file; it includes a newline character at the end of
eachline. These files start with a blank initial line intended to
prevent mail programs from discarding any of the data. The BR column
indicates whether a problem has bounds or ranges: B stands for "has
bounds", R for "has ranges". The BOUND-TYPE TABLE below shows the
bound types present in those problems that have bounds.

The problems below are sorted (according to the ASCII collating sequence) on their names. Unless problem characteristics suggest a more rational order, we suggest using this order for reporting results.

PROBLEM SUMMARY TABLE

Name	Rows	Cols	Nonzeros	Bytes	BR	Optimal Value
25FV47	822	1571	11127	70477		5.5018458883E+03

Several problems have an empty RHS section: BORE3D, CYCLE, GREENBEA, GREENBEB, KB2, RECIPE, and TUFF.

HEARTY THANKS go to the people who supplied the above problems. Michael Saunders provided 13 problems from the Systems Optimization Laboratory at Stanford University: ADLITTLE, AFIRO, BANDM, BEACONFD, BRANDY, CAPRI, E226, ETAMACRO, ISRAEL, PILOT, SHARE1B, SHARE2B, STAIR. Four problems are from a tape that John Reid sent me (David Gay) several years ago: 25FV47, CZPROB, FFFFF800, SHELL. Linus Schrage sent GANGES and SEBA. Bob Fourer supplied 44 problems: 80BAU3B, BORE3D, FIT1D, FIT1P, FIT2D, FIT2P, FORPLAN, GFRD-PNC, GREENBEA, GREENBEB, GROW15, GROW22, GROW7, NESM, PILOT.JA, PILOT.WE, PILOT4, PILOTNOV, RECIPE, SC205, SCAGR25, SCAGR7, SCFXM1, SCFXM2, SCFXM3, SCORPION, SCRS8, SCSD1,SCSD6, SCSD8, SCTAP1, SCTAP2, SCTAP3, SHIP04L, SHIP04S, SHIP08L,SHIP08S, SHIP12L, SHIP12S, SIERRA, STANDATA, STANDGUB, STANDMPS,VTP.BASE. Mauricio Resende provided AGG, AGG2, and AGG3, which were formulated by R. C. Leachman. Gus Gassmann contributed STOCFOR1,STOCFOR2, and STOCFOR3. Nick Gould supplied BLEND, BOEING1, BOEING2,FINNIS, PEROLD, SC105, SC50A, and SC50B from the Harwell collection of LP test problems. Vahid Lotfi submitted LOTFI. With the permission of Ketron, John Tomlin provided BNL1, BNL2, CYCLE, D2Q06C, DEGEN2, DEGEN3,KB2, TUFF, WOOD1P, and WOODW. At the request of Olvi Mangasarian,Rudy Setiono supplied the generator and

description (both written byMichael Ferris) and data for TRUSS. Istvan Maros provided MAROS,
MAROS-R7, and MODSZK1. Irv Lustig supplied PILOT87, which he obtained from John Stone. Marc Meketon submitted DFL001. Robert Hughes supplied
D6CUBE. Problems QAP8, QAP12, and QAP15 are from a generator by Terri Johnson (communicated by a combination of Bob Bixby, Matt Saltzman, and
Terri Johnson).
Thanks also go to Irv Lustig for helpful comments on this index file.

NOTES: we have omitted extra right-hand side vectors from BEACONFD, BRANDY, FFFFF800, ISRAEL; extra bound sets from GREENBEA, GREENBEB, GROW15, GROW22, GROW7, RECIPE; extra free rows from 80BAU3B, BOEING1, BORE3D, E226, FFFFF800, FINNIS, FORPLAN, GANGES, GREENBEA, GREENBEB, MAROS, PILOT, PILOT87, RECIPE, SCTAP1, SCTAP2, SCTAP3, SHARE2B, SHIP04L,
SHIP04S, SHIP08L, SHIP08S, SHIP12L, SHIP12S; and explicit zeros from GROW15, GROW22, GROW7, NESM, SCORPION, SCRS8, SEBA, SIERRA, STAIR. We also negated the cost coefficients in BOEING1, BOEING2, DEGEN2, DEGEN3,
ETAMACRO, FIT1D, FIT2D, GANGES, GROW15, GROW22, GROW7, LOTFI, MAROS, PILOT, PILOT.JA, PILOT.WE, PILOTNOV, SC105, SC50A, SC50B, STAIR. In their original form, these problems are usually maximized. In their modified form, all problems are to be minimized. (PILOT4 appeared to be a minimization problem already).

Problem 25FV47 is sometimes called BP or BP1, and FFFFF800 is sometimes
called POWELL. Problems GREENBEA and GREENBEB differ only in their BOUNDS sections. The names shown above come mostly from the original NAME line; the optimal values are from MINOS version 5.3 (of Sept. 1988)
running on a VAX with default options (except, as described below, for DFL001 and the QAP problems). [Earlier versions of this index file gave
values from earlier versions of MINOS. Prior to 29 April 1987, this index file gave the optimal value from maximizing rather than minimizing
PILOTNOV.]

Note that MINOS control parameters, such as SCALE, PARTIAL PRICE, FEASIBILITY TOLERANCE, OPTIMALITY TOLERANCE, and CRASH OPTION may affect the optimal value that MINOS reports (as may the version of MINOS, the computer, and even the compiler used).

This directory does not provide compressed MPS files for the QAP problems. Instead, source for Terri Johnson's generator and input data
for producing MPS files for QAP8, QAP12, and QAP15 appear in directory lp/generators/qap.

For discussion of some of the above test problems, including sparsity graphs and MINOS performance with and without scaling and partial pricing, see "An Analysis of an Available Set of Linear Programming Test Problems" by Irvin J. Lustig [Tech. Report SOL 87-11, Systems Optimization Laboratory, Dept. of Operations Research, Stanford Univ., Stanford, CA 94305-4022; a shorter version appears in Comput. Opns. Res. vol. 16, no. 2, pp. 173-184, 1989]. Be warned that the reproduction process may have dropped isolated nonzeros from graphs of

the larger problems.

Bob Bixby reports that the CPLEX solver (running on a Sparc station) finds slightly different optimal values for some of the problems. On a MIPS processor, MINOS version 5.3 (with crash and scaling of December 1989) also finds different optimal values for some of the problems. The following table shows the values that differ from those shown above. (Whether CPLEX finds different values on the recently added problems remains to be seen.)

Problem	CPLEX(Sparc)	MINOS(MIPS)
25FV47		5.5018467791E+03

STOCFOR3	-3.9976783944E+04	-3.9976776417E+04

The above CPLEX and MINOS results were both obtained using double-precision IEEE (binary) arithmetic, i.e., arithmetic of precision similar to the VAX double precision with which the MINOS 5.3 results in the PROBLEM SUMMARY TABLE were computed.

The old problem GUB was the same as CZPROB (except for the NAME line) and hence is withdrawn.

STANDGUB includes GUB markers; with these lines removed (lines in the expanded MPS file that contain primes, i.e., that mention the rows 'EGROUP' and 'ENDX'), STANDGUB becomes the same as problem STANDATA; MINOS does not understand the GUB markers, so we cannot report an optimal value from MINOS for STANDGUB. STANDMPS amounts to STANDGUB with the GUB constraints as explicit constraints.

STOCFOR1,2,3 are stochastic forestry problems from Gus Gassmann. To quote Gus, "All of them are seven-period descriptions of a forestry problem with a random occurrence of forest fires, and the size varies according to the number of realizations you use in each period." STOCFOR1 "is the deterministic version, STOCFOR2 has 2 realizations each in periods 2 to 7, and the monster STOCFOR3 has 4,4,4,2,2, and 2 realizations, respectively." The compressed form of STOCFOR3 would be 652846 bytes long, so requesting STOCFOR3 will instead get you a bundle

of about 174 kilobytes that includes source for Gus's program, the data files for generating STOCFOR3 and a summary of "A Standard Input Format for Multistage Stochastic Linear Programs" by J.R. Birge, M.A.H. Dempster, H.I. Gassmann, E.A. Gunn, A.J. King, and S.W. Wallace [COAL Newsletter No. 17 (Dec. 1987), pp. 1-19]. Data files are also included for generating versions of STOCFOR1,2 that have more decimal places than the versions in lp/data.

For STOCFOR3, in 1990, Bob Bixby reported an optimal objective value of -3.9976785944E+04. In July 2005, Bill Hager reported an error in the eighth decimal place of this value, as computed by a later version of CPLEX and by Hager's own solver. With the a recent CPLEX, I (dmg) get the same objective value that Hager reported and have adjusted the value shown above in the CPLEX(Sparc) column accordingly.

Concerning the problems he supplied, Nick Gould says that BLEND "is is a variant of the [oil refinery] problem in Murtagh's book (the coefficients are different) which I understand John Reid obtained from the people at NPL (Gill and Murray?); they were also the original sources for the SC problems"; BOEING1 and BOEING2 "have to do with flap settings on aircraft for economical operations"; PEROLD "is another Pilot model (Pilot1)"; and FINNIS "is from Mike Finnis at Harwell, a model for the selection of alternative fuel types."

BOEING1 and BOEING2 were originally mixed-integer programming problems.
The COLUMNS section of BOEING1 had

```
    INTBEG    'MARKER'                 'INTORG'
```

between the coefficients for columns GRDTIMN6 and N1001AC1, and that BOEING2 had such a line between columns GRDTIMN4 and N1003AC1. Both had

```
    INTFIN    'MARKER'                 'INTEND'
```

just before the start of the ROWS section. These 'MARKER' lines have been removed. These problems also had a few rows defined as linear combinations of other rows. These rows are now given explicitly, since
the compression/expansion programs do not understand D lines in the ROWS
section.

LOTFI, says Vahid Lotfi, "involves audit staff scheduling. This problem
is semi real world and we have used it in a study, the results of which
are to appear in Decision Sciences (Fall 1990). The detailed description of the problem is also in the paper. The problem is actually an MOLP with seven objectives, the first is maximization and the other six are minimization. The version that I am sending has the aggregated objective (i.e., z1-z2-z3-z4-z5-z6-z7)."

On the problems supplied by John Tomlin, MINOS 5.3 reports that about 10% to 57% of its steps are degenerate:

Name	Steps	Degen	Percent
BNL1	1614	169	10.47
BNL2	4914	906	18.44
CYCLE	3156	1485	47.05
D2Q06C	42417	4223	9.96
DEGEN2	1075	610	56.74
DEGEN3	6283	3299	52.51
KB2	82	29	35.37
TUFF	745	345	46.31

WOOD1P	1059	471	44.48
WOODW	4147	1604	38.68

Concerning PILOT87, Irv Lustig says, "PILOT87 is considered (by John Stone, at least) to be harder than PILOT because of the bad scaling in the numerics."

Requesting TRUSS will get you a bundle of Fortran source and data for generating an MPS file for TRUSS, a problem of minimizing the weight of a certain structure. The bundle also includes a description of the problem.

DFL001, says Marc Meketon, "is a 'real-world' airline schedule planning (fleet assignment) problem. This LP was preprocessed by a modified version of the KORBX(r) System preprocessor. The problem reduced in size (rows, columns, non-zeros) significantly. The row and columns were randomly sorted and renamed, and a fixed adjustment to the objective function was eliminated. The name of the problem is derived from the initials of the person who created it."

Of D6CUBE, Robert Hughes says, "Mike Anderson and I are working on the problem of finding the minimum cardinality of triangulations of the 6-dimensional cube. The optimal objective value of the problem I sent you provides a lower bound for the cardinalities of all triangulations which contain a certain simplex of volume 8/6! and which contains the centroid of the 6-cube in its interior. The linear programming problem is not easily described."

Concerning the problems he submitted, Istvan Maros says that MAROS is an industrial production/allocation model about which "the customer does not want to reveal the exact meaning". MAROS-R7 is "an interesting real-life LP problem which appeared hard to some solvers." It "is an image restoration problem done via a goal programming approach. It is structured, namely, its first section is a band matrix with the dominating number of nonzeros, while the second section is also a band matrix with bandwidth equals 2 and coefficients +1, -1. The problem is a representative of a family of problems in which the number of rows and the bandwidth of the first section can vary. This one is a medium size problem from the family. MAROS-R7 became available in cooperation with Roni Levkovitz and Carison Tong." MODSZK1 is a "real-life problem" that is "very degenerate" and on which a dual simplex algorithm "may require up to 10 times" fewer iterations than a primal simplex algorithm. It "is a multi-sector economic planning model (a kind of an input/output model in economy)" and "is an old problem of mine and it is not easy to recall more."

** On an IEEE-arithmetic machine (an SGI 4D/380S), I (dmg) succeeded in getting MINOS 5.3 to report optimal objective values, 1.1261702419E+07 and 1.1249281428E+07, for DFL001 only by starting with LOAD files derived from the solution obtained on the same machine by Bob

Vanderbei's ALPO (an interior-point code); starting from one of the resulting "optimal" bases, MINOS ran 23914 iterations on a VAX before reporting an optimal value of 1.1253287141E+07. When started from the same LOAD file used on the SGI machine, MINOS on the VAX reported an optimal value of 1.1255107696E+07. Changing the FEASIBILITY TOLERANCE to 1.E-10 (from its default of 1.E-6) led MINOS on the SGI machine to report "optimal" values of 1.1266408461E+07 and 1.1266402835E+07. This
clearly is a problem where the FEASIBILITY TOLERANCE, initial basis, and
floating-point arithmetic strongly affect the "optimal" solution that MINOS reports. On the SGI machine, ALPO with SPLIT 3 found

```
 primal:  obj value =  1.126639607e+07      FEASIBLE   ( 2.79e-09 )
 dual:    obj value =  1.126639604e+07      FEASIBLE   ( 1.39e-16 )
```

Bob Bixby reports the following about his experience solving DFL001 with CPLEX:

> First, the value for the objective function that I get running defaults is 1.1266396047e+07, with the following residuals:
>
> Max. unscaled (scaled) bound infeas.: 4.61853e-14 (2.30926e-14)
> Max. unscaled (scaled) reduced-cost infeas.: 6.40748e-08 (6.40748e-08)
> Max. unscaled (scaled) Ax-b resid.: 4.28546e-14 (4.28546e-14)
> Max. unscaled (scaled) c_B-B'pi resid.: 8.00937e-08 (8.00937e-08)
>
> The L_infinity condition number of the (scaled) optimal basis is 213737. I got exactly the same objective value solving the problem in several different ways. I played a bit trying to get a better reduced-cost infeasibility, but that seems hopeless (if not pointless) given the c-Bpi residuals.
>
> Just as an aside, this problem exhibits very interesting behavior when solved using a simplex method. I ran reduced-cost pricing on it in phase I, with the result that it took 465810 iterations to get feasible. Running the default CPLEX pricing scheme, the entire problem solved in 94337 iterations (33059 in phase I) on a Sparcstation. Steepest-edge pricing (and a different scaling) took 25803 iterations. This is a nasty problem.

Notes from Michael Saunders describing experience with MINOS on the problems he provided are available via the netlib request

```
    send minos from lp/data
```

  FIT1D, FIT1P, FIT2D, FIT2P: Bob Fourer himself.

Concerning FIT1D, FIT1P, FIT2D, FIT2P, Bob Fourer says
> The pairs FIT1P/FIT1D and FIT2P/FIT2D are primal and dual versions of the same two problems [except that we have negated the cost coefficients of the dual problems so all are minimization problems]. They originate from a model for fitting linear inequalities to data, by minimization of a sum of piecewise-linear penalties. The FIT1 problems are based on 627 data points and 2-3 pieces per primal pl penalty term. The FIT2 problems are based on 3000 data points (from a different sample altogether) and 4-5 pieces per pl term.

To get C source for the compression program, issue the netlib request

    send mpc.src from lp/data

Contributions are welcome, either problems in MPS format or source code for problem generators. Send questions, comments, contributions to

Cross reference: Eberhard Kranich's extensive bibliography on interior-point methods is available from netlib. For details, ask netlib to

        send index from bib

Change log...
  1 June 1987: mpc.src added.
  6 May 1988: GREENBEA, GREENBEB, AGG, AGG2, AGG3 added.
  25 June 1988: STOCFOR1,2 added
  16 Jan. 1989: STOCFOR3 added; bound and range information added to index file; MINOS 5.3 optimal values inserted.
  23 Jan. 1989: correction to bound-handling portion of STOCFOR3 source code. This does not affect STOCFOR3 itself, but is relevant to other uses of this Fortran code.
  6 April 1989: BLEND BOEING1 BOEING2 FINNIS PEROLD SC105 SC50A SC50B added.
  27 June 1989: CYCLE KB2 LOTFI TUFF WOOD1P WOODW added.

30 Oct. 1989: BNL1 BNL2 D2Q06C DEGEN2 DEGEN3 added.

30 Nov. 1989: options -s and -S added to emps.c so you can request several problems at once and split them into files named by the problem name (in upper case with -S or in lower case with -s). For use with these new options, the NAME line of several problems has now been modified so that the first word after "NAME" gives the name specified above for the problem. Now all compressed MPS files have this property. The problems whose NAME line was thus modified are BLEND, BOEING1, FINNIS, FORPLAN, PEROLD, PILOT, PILOTNOV, STANDGUB, STANDMPS, STOCFOR1, and STOCFOR2.

22 Jan. 1990: all material described here made available by anonymous ftp from research.att.com (now netlib.bell-labs.com, directory /netlib/lp/data).

31 Jan. 1990: FIT1D, FIT1P, FIT2D, FIT2P added.

8 Feb. 1990: emps.c, emps.f modified to quietly ignore extra lines at
the end of a compressed MPS file (e.g., those that mailers add).

15 Feb. 1990: added table of optimal values reported by Bob Bixby.

26 Feb. 1990: TRUSS added.

30 Apr. 1990: ascii (table of ASCII codes) added; MINOS(MIPS) optimal values added to this index file.

15 June 1990: MAROS and PILOT87 added.

11 Oct. 1990: DFL001 added.

9 Jan. 1991: Bixby's remarks about DFL001 added to index.

6 June 1991: emps.c and emps.f adjusted to pass "mystery lines" through, for possible use in conveying other problem information (in connection with mpc -m). [For years emps.c has had this ability; today's change fixes a bug with mystery lines just before ENDATA.]

4 Sept. 1991: "Kennington" problems made available by ftp from netlib.

21 Oct. 1991: minor cleanups...
1. BOEING1: remove duplicate upper bounds for columns N1019AC3 and N1019AC4.
2. PILOT: remove 8 duplicate right-hand side values for row BTRB01.
3. PILOT87: remove lower bound of 49.5 on U[OG]ST0[12], which are subsequently fixed at 99 (UOST[12]) or 65.4.

2 May 1992: emps.c ANSIfied (with #ifdef KR_headers lines for old-style C compilers); new option -b changes blanks within names to underscores (and changes blank RHS names to RHS, etc.) -- for awk scripts and other programs that assume no blanks in names.

4 Feb. 1993: STOCFOR3 updated. STOCFOR3 and the other problems you can generate with the data in the stocfor3 bundle are the same numerically as before (but with different row and column labels). The update (courtesy of Gus Gassmann) fixes some bugs in other uses of the generator and expands your options in using the generator. The previous version is now stocfor3.old.

26 March 1993: D6CUBE added.

17 Jan. 1994: MAROS-R7 and MODSZK1 added.

12 April 1996: QAP8, QAP12, QAP15 added to result table; directory lp/generators/qap added for generating these problems.

7 August 2005: objective value for STOCFOR3 in CPLEX(Sparc) column of readme adjusted; some file names in "read.me" in the stocfor3 bundle corrected; portability tweaks to mpc.src.
